NEW SPEEDWAY

Every investment edge decays. Can the research process improve?

An AI research team that tests investment ideas, remembers the results and uses them to choose what to investigate next.

Strategies come and go. The research process accumulates knowledge.

Strategy 1	Strategy 2	Strategy 3	Strategy 4	Strategy 5
retired	retired	reduced	live on paper	not yet found

One research process keeps running underneath: what was tried, what happened, what to ask next

Pre-implementation design, October 2026. No investment performance is claimed.

Today’s failed backtest should improve tomorrow’s question.

Speedway keeps what was tried, what happened and what to investigate next. One research journey:

QUESTION

Do volatility-targeting funds create predictable selling pressure?

→

EVIDENCE

The flow effect shows up. The hypothesis is supported.

→

TRADE

The selling pressure appears real, but transaction costs absorb the return. Rejected.

→

NEXT

Can we identify when the pressure is large enough to trade economically? Define the test before evaluating it on fresh observations.

The trade failed. The research got better. The failed trade becomes evidence for the next decision.

Illustrative journey from the design proposal. The hypothesis, the evidence and the rejection all stay on the record.

A profitable strategy can have the wrong explanation.

So the explanation, the trade and the research method are judged separately, each on its own record.

THE HYPOTHESIS

Was the explanation supported?

Judged by its own predictions, committed before the outcome was knowable.

THE STRATEGY

Did the trade make money after costs?

Judged on its own forward record, net of modelled costs, within risk limits.

THE RESEARCH METHOD

Did the researcher produce useful work?

Judged on research quality for the budget, never on a count of appealing backtests.

An agent proposes a better research method. We compare it with its predecessor on new tasks, including the cost.

A right explanation can lose money. A winning trade can rest on a wrong one. Speedway records which, and acts on each.

No score in one competition feeds another unless a recorded decision says so.

Use existing tools. Build the research process.

The core tools already exist. The missing part is the system that directs them and learns from the results.

WE WILL USE EXISTING RESOURCES FOR

- Open-source backtesting
- Existing AI models
- Market data and document sources
- Established workflow and storage software
- Suitable paper-trading tools

WE WILL BUILD SPEEDWAY TO

- Turn investment questions into defined experiments
- Propose and challenge ideas
- Preserve evidence, including failed tests
- Coordinate research within budgets
- Evaluate strategies and propose what happens next

We are not building another backtesting engine or training a foundation model. We are building the system that directs the research and learns from its results.

Specific products remain under evaluation. The reuse strategy does not depend on which ones are chosen.

More autonomous research. Explicit human control.

Agents can investigate and propose. Budget and capital decisions remain governed.

AGENTS MAY, WITHIN A MANDATE

- Investigate changes in the world and patterns in data
- Propose hypotheses and strategies
- Run backtests and paper tests inside a budget
- Propose improved research methods and test them against earlier versions
- Register routine hypotheses after an independent check

ONLY YOU DECIDE

- Every grant of budget and scope
- Every allocation of paper capital, up or down
- The standard everything is judged by
- Stopping new spending, at any moment
- Any change to the rules themselves

Every change is independently checked and recorded. You can see why something changed, stop new spending, and recover without losing the record.

An agent holds no right it was not granted. A new agent version inherits research, never permissions.

What we would demonstrate first.

Give Speedway an investment question and a research budget. Watch it propose competing tests, run them, compare the evidence and recommend the next experiment. Inspect every result and every dollar spent.

Give it a question and a budget

An investment question and a research budget

It proposes competing tests

Several ways to test the idea, each with a stated reason

It runs them

On historical data, through an existing backtester

It compares the evidence

What held up, what failed, what it cost

It recommends the next experiment

Chosen from the evidence, not from a hunch

WHAT IT PROVES

The research loop works end to end, every result and every dollar spent is inspectable, and the evidence changes what is asked next.

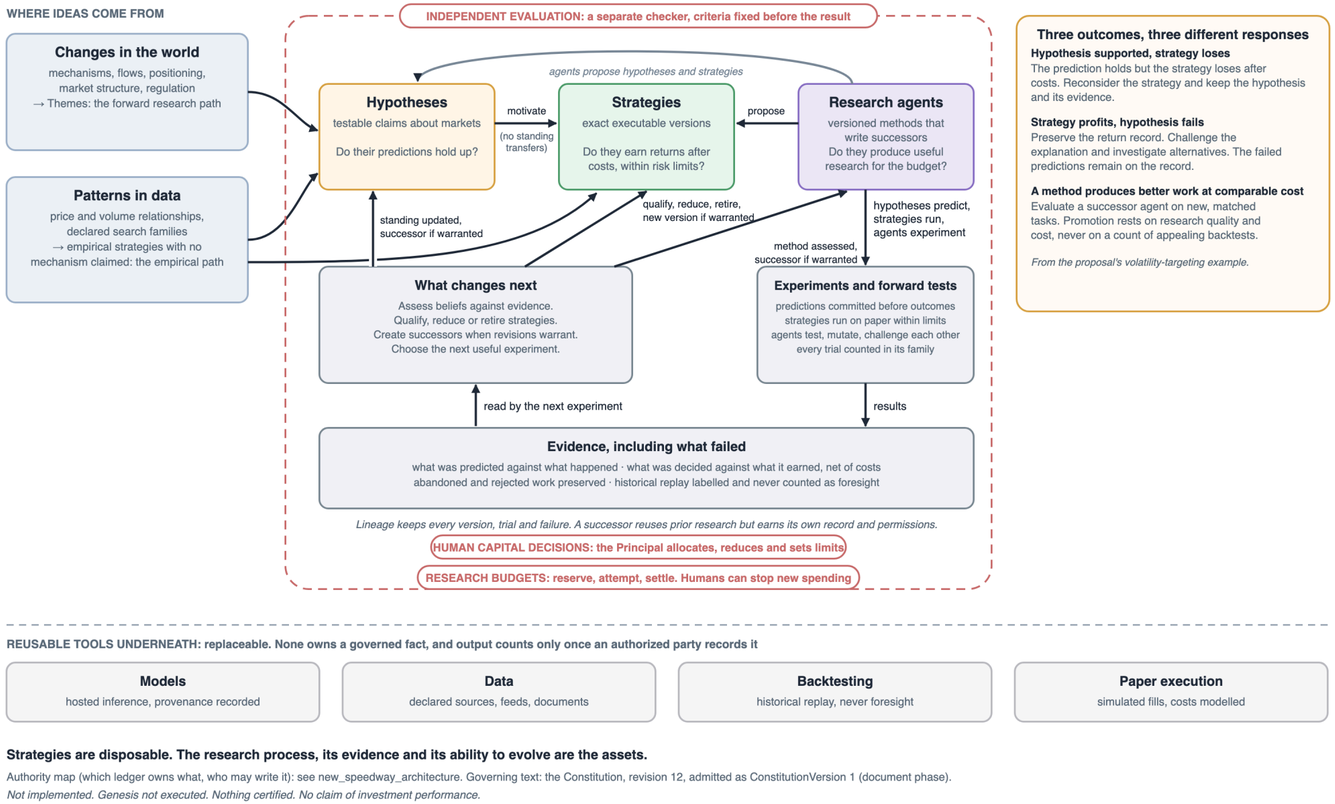

WHAT IT DOES NOT PROVE

An edge. Replay rejects bad ideas. Only forward results can support one.

Underneath: independent checks on every change, and recovery from the record if a run is interrupted. Design admitted on paper, October 2026. No code, no live data, no capital.

APPENDIX

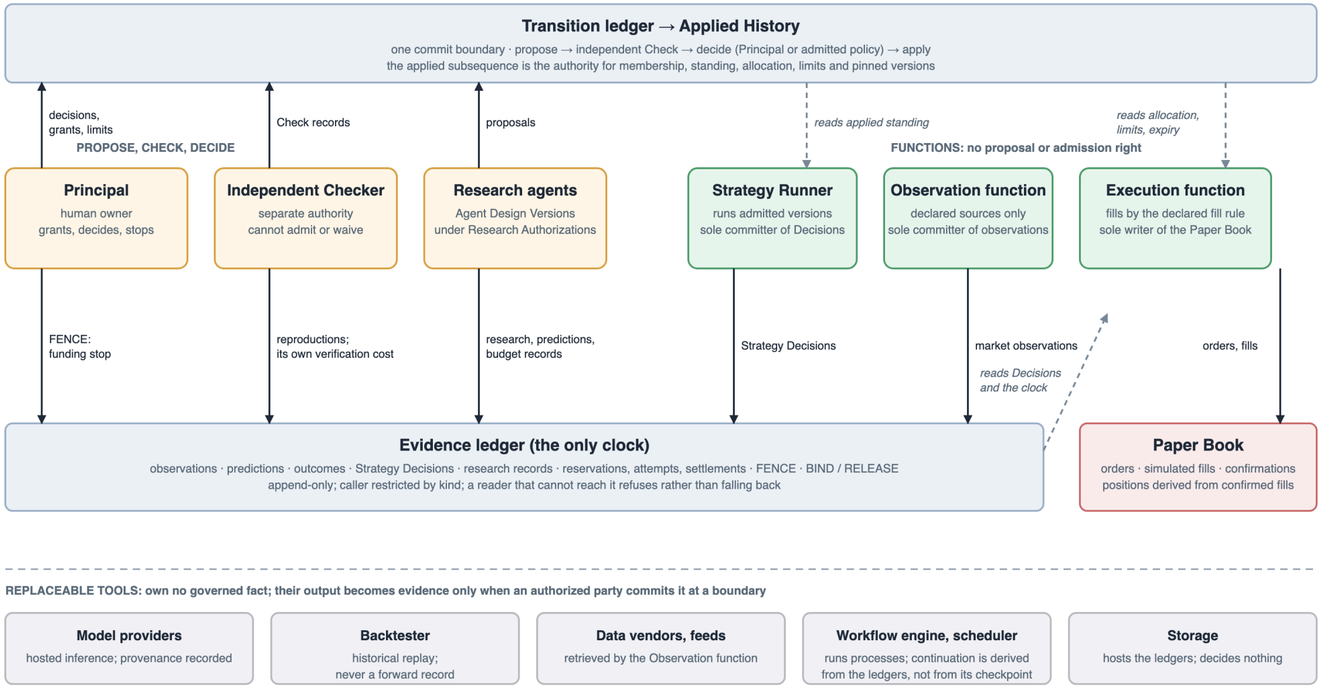

How the research process evolves

For questions. The main slides translate this into outcomes.

APPENDIX

Architecture: who may write what

Three append-only ledgers, one commit boundary each. Everything else (caches, dashboards, agent memory, projections) is derived and has no vote.
Every consequential change is a Transition: proposed with an immutable content and base state, independently checked, decided, applied in total order. A stale base is refused.
Research budgets are reserved before work and settled after; capital goes only to exact Strategy Versions on their own forward record; a successor starts at zero.

Source: docs/doctrines/new_speedway_constitution.md (revision 12, admitted as ConstitutionVersion 1); architecture.md §4.

Three records, one commit boundary each. Tools are replaceable and own nothing. The Constitution governs this map.
